No. is the number of results predicted by chance to have a score greater than or equal to the score of the result being printed, and is derived by analysis of the total score distribution.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        DB DB

Has a role in chromosome segregation by recruiting condensin and arki kinase to appropriate sites as the cell progresses through mitosis.

SUBCELLULAR LOCATION: Nuclear. Interacts with the outer centromeric regions of the chromosomes during interphase. Chromatid separation moves to the middle of the spindle.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        centromeric regions of the chromosomes du

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Evaluation of
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            'Carpenter-Waziri syndrome results
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Med.
magnt be account the cause of Carpenter-Waziri hemoglobin h inclusions.

DISEASE: Defects in ATRX are the cause of Carpenter-Waziri syndrome (CWS), an X-linked recessive condition characterized by moderate mental retardation, short stature, brachydactyly with moderate mental retardation, short stature, brachydactyly with excessive skin creases, and widening of the knuckles.
                                                                                                                                                                                                                                                                                                                                  erythrocyte inclusions.

DISEASE: Defects in ATRX are the cause of Sutherland-Haan mental retardation syndrome (SHS) [MIM:309470]. It is mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe mental retardation with spastic characterized by severe menta
                                                                                                                                                                       paraplegia, microcephaly, short stature and cryptorchidism. DISEASE: Defects in ATRX are a cause of Smith-Fineman-Myers syndrome (SFM) [MM:309580]. Clinical features include severe mental retardation, microcephaly, growth failure, facial anomalies and bilateral cryptorchidism. Due to the clinical overlap with ATR-X syndrome, some patients originally diagnosed as having SFM, might be affected by a variant of ATR-X syndrome which lack

  (Clostridium argentinense) type G neurotoxin: genealogical comparison with other clostridial neurotoxins.";
Biochim. Biophys. Acta 1216:487-491 (1993).

-: FUNCTION: BOTULINUS TOXIN ACTS BY INHIBITING NEUROTRANSMITTER RELEASE. IT BINDS TO DERIPHERAL NEURONAL SYNAPSES, IS INTERNALIZED AND MOVES BY RETROGRADE TRANSPORT UP THE AXON INTO THE SPINAL CORD WHERE IT CAN MOVE BETWEEN POSTSYNAPTIC AND PRESYNAPTIC NEURONS. IT INHIBITS NEUROTRANSMITTER RELEASE BY ACTING AS A 77NO ENDOPEDTIDASE
                                                                                                                       Campbell

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         DENTIFICIATION IN A CONDENSIN COMPLEX WITH SMC4;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            QUENCE FROM N.A.
                                                         Chromosomes is observed in late telophase.

DOMAIN: The flexible hinge domain, which separates the large intramolecular coiled coil regions, allows the heterodimerization should be separated intramolecular coiled coil regions, allows the heterodimerization should be separated intramolecular coiled coil regions, and the heterodimer (By similarity). SIMILARITY: Belongs to the SMC family. SMC2 subfamily.
                                                                                                                                                         BRN1, YCS4 and YCG1/YCS5.
SUBCELLULAR LOCATION: Nuclear and cytoplasmic. In interphase cells, the majority of the condensin complex is found in the cytoplasm; while a minority of the complex is associated with chromatin. A subpopulation of the complex however remains associated with chromosome foci in interphase cells. During mitosis, most of the condensin complex is associated with the chromatin. At the onset of prophase, condensin associates with chromosome arms and to chromosome condensation. Dissociation from the chromosome arms and to chromosome condensation.
                                                                                                                                                                                                                                                                                                                                  Cell Biol. 149:811.824 (2000).

Cell Biol. 149:811.824 (2000).

FUNCTION: Central component of the condensin complex, a complex required for conversion of interphase chromatin into mitotic-like condense for conversion of interphase chromatin probably introduces positive supercoils into relaxed DNA in the presence of type I topoisomerases and converts nicked DNA into positive knotted forms in the presence of type II topoisomerases.

SUBUNIT: Forms an heterodimer with SMC4. Component of the condensin complex, which contains the SMC2 and SMC4 heterodimer, and three non SMC subunits that probably regulate the complex:

TINA recognition properties of the N-terminal DNA binding domain within the large subunit of replication factor C.";

RT Within the large subunit of replication factor C.";

RND Nucleic Acids Res. 26:3877-3882 (1998).

CC LOUNCTION: THE ELONGATION OF PRIMED DNA TEMPLATES BY DNA POLYMERASE DELTA AND EPSILON REQUIRES THE ACTION OF THE ACCESSORY PROTEINS COMMENT OF THE PRIMET BINDS TO THE PRIMER-TEMPLATE COMMENT OF THE PRIMER PRIMER PROTEINS COLL PLAY A ROLE IN DNA TRANSCRIPTION ELEMENT AS WELL AS OTHER COMMENT OF THE PART FORMS A REPLICATION AND/OR REPAIR. CAN BIND COMMENT OF THE POST PROMED DNA.

CC SINGLE- OR DOUBLE-STRANDED DNA.

CC FUNCTION: INTERACTS WITH C-TERMINUS OF PCNA. 5' PHOSPHATE RESIDUE IS REQUIRED FOR BINDING OF THE N-TERMINAL DNA-BINDING DOMAIN TO COMPLEX DNA, SUGGESTING A ROLE IN RECOGNITION OF NON-PRIMER COMPLEX DNA, SUGGESTING A ROLE IN RECOGNITION AND/OR REPAIR.

CC -I- SUBUNIT: HETEROPENTAMER OF SUBUNITS OF 140/145, 40, 38, 37, AND COMPLEX DNA THAT FORMS A COMPLEX WITH PCNA IN THE PRESENCE OF ATP.
                                                                                                                                                                                                                                                                                       EMBL; AF04250; AAB99788.1; -.

"Mapping of the novel protein kinase catalytic domain of Dictyostelium myosin II heavy chain kinase A.";

J. Biol. Chem. 272:6846-6849(1997).

-i- FUNCTION: PHOSPHORYLATES THREONINE IN THE C-TERMINAL TAIL REGION OF MYOSIN II HEAVY CHAIN. THIS PHOSPHORYLATION IS CRITICAL IN REGULATING THE ASSEMBLY AND DISASSEMBLY OF MYOSIN II FILAMENT. REQUIRES AUTOPHOSPHORYLATION FOR ACTIVITY.

                                       DOMAIN: THE RODLIKE TAIL SEQUENCE IS HIGHLY REPETITIVE, SHOWING CYCLES OF A 28-RESIDUE REPEAT PATTERN COMPOSED OF 4 HEBTAPEPTIDES CHARACTERISTIC FOR ALPHA-HELICAL COILED COILS.

PTM: TWO CYSTEINE RESIDUES IN THE S1 DOMAIN ARE SELECTIVELY ALKYLATED AND ARE REQUIRED FOR MYOSIN ATPASE ACTIVITY.

MISCELLANEOUS: EACH MYOSIN HEAVY CHAIN CAN BE SPLIT INTO 1 LIGHT MEROMYOSIN (LMM) AND 1 HEAVY MEROMYOSIN (HMM). IT CAN LATER BE SPLIT FURTHER INTO 2 GLOBULAR SUBFRAGMENTS (S1) AND 1 ROD-SHAPED SUBFRAGMENT (S2).

SIMILARITY: Contains 1 myosin-11ke globular head domain.
                                                                                                                                                                                                                  SUBUNIT: MUSCLE MYOSIN IS A HEXAMERIC PROTEIN THAT CONSISTS OF 2 HEAVY CHAIN SUBUNITS (MLC) 2 ALKALI LIGHT CHAIN SUBUNITS (MLC) AND 2 REGULATORY LIGHT CHAIN SUBUNITS (MLC-2).

SUBCELLULAR LOCATION: Thick filaments of the myofibrils. DEVELOPMENTAL STAGE: ABUNDANTLY PRESENT IN FETAL SKELETAL MUSCLE AND NOT PRESENT OR BARELY DETECTABLE IN HEART AND ADULT SKELETAL

Neurons may die as a normal physiological process during development or as a pathological process in diseases. The best-understood mechanism of neuronal cell death is apoptosis, which is regulated by an evolutionarily conserved cellular pathway that consists of the caspase family, the Bcl-2 family, and the adaptor protein Apaf-1.

Apoptosis, however, may not be the only cellular mechanism that regulates neuronal cell death. Neuronal cell death may exhibit morphological features of autophagy or necrosis, which differ from that of the canonical apoptosis. This review evaluates the evidence supporting the existence of alternative mechanisms of neuronal cell death and proposes the possible existence of an evolutionarily conserved pathway of necrosis.

Topoisomerase inhibitors are among the most efficient inducers of leading apoptosis. The main pathways topoisomerase-mediated DNA damage to cell death involve activation of caspases in the cytoplasm by proapoptotic molecules released from mitochondria. In some cells, apoptotic response also involves the death receptor Fas (APO-1/CD95). The engagement of these apoptotic effector pathways is tightly controlled by upstream regulatory pathways that respond to DNA lesions-induced by topoisomerase inhibitors in cells undergoing apoptosis. These include the proapoptotic Chk2, c-Abl and pathways, the survival PI(3)kinase-Akt-dependent pathway and the transcription factors p53 and NF-kappaB. Initiation of cellular responses to DNA lesions-induced by topoisomerase inhibitors is ensured by the protein kinases DNA-PK, ATM and ATR, which bind to DNA breaks. These kinases commonly called "DNA sensors" mediate their effects (DNA repair, cell cycle arrest and/or apoptosis) by phosphorylating a large number of substrates, including several downstream kinases such as c-Abl and the checkpoint protein Chk2. c-Abl induces apoptosis by activating cell death pathways (e.g., SAPK, p53 and p73) and inhibiting cell survival pathways [e.g., PI(3)kinase]. The DNA-damage regulating kinase Chk2, in addition to its role in cell cycle arrest and/or DNA repair, can induce apoptosis by phosphorylation/activation of the promyelocytic leukemia (PML) protein and p53. Finally, we will review the recent observations that support a role for topoisomerases in chromatin fragmentation during the execution phase of apoptosis.

Granule cells of the cerebellum constitute the largest homogeneous neuronal population of mammalian brain. Due to their postnatal generation and the feasibility of well characterized primary in vitro cultures, cerebellar granule cells are a model of election for the study of cellular and molecular correlates of mechanisms of survival/apoptosis and neurodegeneration/neuroprotection. The present review mainly deals with recent data on mechanisms and factors promoting survival or apoptotic elimination of cerebellar granule neurons, with a particular focus on the molecular correlates at the level of gene expression and induction of cellular signal pathways. The in vivo development is first analysed with particular reference to the role played by several neurotrophic factors and by the NMDA subtype of glutamate receptor. Then, mechanisms of survival/apoptosis are examined in the model of primary in vitro cultures, where the role of neurotrophins acting on cerebellar granule cells is followed by the large deal of data coming from the paradigm of potassium/serum withdrawal. The role of some key genes of the Bcl family, of some kinase systems and of transcriptional factors is primarily highlighted. Furthermore, the involvement of mitochondria, free radicals and proteases of the caspase family is considered. Finally, the use of cerebellar granule neurons in primary culture to experimentally address the issue of neurodegeneration and pharmacological neuroprotection is considered, with some comments on models at the borderline between necrosis apoptosis, such as the excitotoxic neuronal damage. The overlapping of cellular signal pathways activated in granule neurons unrelated stimuli, such as apparently neurotrophins neurotransmitters/neuromodulators is stressed to put into light the special 'trophic' role played by activity in neurons. Finally, the advantage of designing and performing conceptually equivalent experiments on cerebellar granule neurons during development in vivo and in vitro, is stressed. On the basis of the reviewed material, it is concluded that cerebellar granule neurons have acquired a special position in modern neuroscience as one of the most reliable models for the study of neural development, function and pathology.

                                       helix-loop-helix proteins, inhibit
  Id proteins
                antagonize
                               basic
differentiation, and enhance cell proliferation. In this study we compared
the expression of Id-1, Id-2, and Id-3 in the
normal pancreas, in pancreatic cancer, and in chronic pancreatitis (CP).
Northern blot analysis demonstrated that all three Id mRNA species were
expressed at high levels in pancreatic cancer samples by comparison with
normal or CP samples. Pancreatic cancer cell lines frequently coexpressed
all three Ids, exhibiting a good correlation between Id mRNA and protein
levels, as determined by immunoblotting with highly specific anti-Id
antibodies.
              Immunohistochemistry using
                                              these
                                                      antibodies
demonstrated the presence of faint {\rm Id}\text{-}1 and {\rm Id}\text{-}2 immunostaining in pancreatic ductal cells in the normal pancreas, whereas
Id-3 immunoreactivity ranged from weak to strong. In the cancer tissues, many of the cancer cells exhibited abundant Id-1, Id-
2 , and Id-3 immunoreactivity. Scoring on the basis of percentage of
positive cells and intensity of immunostaining indicated that Id-
1 and Id-2 were increased significantly in the cancer
cells by comparison with the respective controls. Mild to moderate Id
immunoreactivity was also seen in the ductal cells in the CP-like areas
adjacent to these cells and in the ductal cells of small and interlobular
ducts in CP. In contrast, in dysplastic and atypical papillary ducts in CP,
Id-1 and Id-2 immunoreactivity was as significantly
elevated as in the cancer cells. These findings suggest that increased Id
expression may be associated with enhanced proliferative potential of
pancreatic cancer cells and of proliferating or dysplastic ductal cells in
CP.

Record type: Completed

As many other nuclear markers, e.g. steroid receptors, Ki-67 epitopes are differentially expressed in tumour cell nuclei. It is unclear whether this phenomenon represents tumour cell heterogeneity, different stages of the cell-cycle or a biological phenomenon with prognostic impact. We analysed primary adult soft tissue sarcomas (ASTS), formalin-fixed, paraffin-embedded, by APAAP and LSAB immunohistochemistry, epitope retrieval technique and 2 anti-Ki-67 antibodies (MIB-1 and Ki-S-5). Expression was evaluated by 4 indexes/1000 tumour cells: a) A-index: sum of all (weak, moderate and strong stained) Ki-67-nuclei, b) the weighed R-index: sum of all strong stained Ki-67+ nuclei x3, moderate stained nuclei x2 and weak stained nuclei x1, c) ID1-index: sum of all strong stained Ki-67+ nuclei, and d) ID2 -index: sum of all strong and moderate stained Ki-67+ nuclei. Prognostic impact was analysed by Kaplan-Meier and logrank statistics with respect to overall survival. Quantitative Ki-67 expression did not vary significantly if determined by MIB-1 or Ki-S-5. The A-index turned out to be the strongest prognostic parameter within the whole group of ASTS as well as within each single sarcoma type investigated. Significant (p < 0.05) correlations between A-index and overall survival existed in LMS, LPS, MFH, SS, while a trend to significance (p = 0.06) was observed in MPNST. Quantitative evaluation of all three differential expression levels is necessary to obtain the most

comprehensive prognostic informations of proliferation markers in ASTS.

RON is a receptor protein tyrosine kinase belonging to the hepatocyte growth factor (HGF) receptor family. Using Recepteur d'Origine Nantais (RON) transfected cell lines, Macrophage Stimulating Protein (MSP) was identified as the ligand of RON. RON is synthesized as a single chain precursor, which subsequently is cleaved to yield a disulfide-linked heterodimer, with a 40-kDa alpha chain and a 150-kDa beta chain. Activation of RON by MSP results in cell migration, shape change, and proliferation. The present work centers on the production and characterization of two monoclonal antibodies (MAbs) to RON called ID-1 and ID-2. Antibodies were generated by immunization of mice with Madin-Darby Canine Kidney (MDCK) cells expressing human RON (clone RE7). Both antibodies recognized the mature and precursor form of RON. The specificity of the anti-RON antibodies was confirmed using a hepatocarcinoma cell line HepG2 expressing both task MET and RON receptors. Specific immunoprecipitation with ID-1 and ID-2 or antibody followed by Western blotting under reducing conditions with rabbit polyclonal antibodies against RON and MET showed that our anti-RON antibodies recognize specifically the RON receptor. Ligand binding experiments showed that both antibodies are able to block the binding of radiolabeled MSP to RON and showed also that the antibodies recognize two different epitopes in the molecule. The blocking of MSP binding to RON by the anti-RON antibodies was confirmed by inhibition of cell migration induced by MSP in HT-29-D4 cells. Significant immunostaining was not observed in any subpopulation of whole Significant immunostaining was not observed in any suppopulation of whole blood with either ID-1 or ID-2. We analyzed the expression of RON receptor in a number of human hematopoietic and nonhematopoietic cells lines by flow cytometry. We found a strong mean of fluorescence intensity (MFI) in colon adenocarcinoma cells SW620 and HT-29-D4, low MFI in SVK14 and HepG2 cells, and no immunostaining in melanoma, lymphoma, and leukemia cells. Immunohistochemistry revealed that RON was expressed in germinal centers of tonsil, in skin, small intestine, and colon. These antibodies defined RON as CDw136 during the last leucocyte typing VI.

Record type: Completed

Although basic helix-loop-helix (bHLH) proteins play an important role in transcriptional control in many cell types, the role of HLH proteins in Schwann cells has yet to be assessed. In this study, we have analyzed the expression of the dominant negative HLH genes, Id1 to Id4 and the class A gene REB, during Schwann cell development. We found that mRNA derived from these genes was present in the Schwann cell lineage throughout development including embryonic precursors and mature cells. The mRNA levels were not significantly regulated during development. Nevertheless, by using antibodies against the four different Id proteins, we found clear regulation of some of these genes at the protein level, in particular Id 2, 4, and REB, both in amount and nuclear/cytoplasmic

localization. All these proteins are found in the nuclei of Schwann cell precursors but are not seen in nuclei of Schwann cells of newborn nerves. We observed extensive overlap in Id expression, especially in Schwann cell precursors that co-expressed all four Id proteins and REB. We also showed that Id 1 and 2 were up-regulated as Schwann cells progressed through the cell cycle. These data indicate that HLH transcription factors act as regulators of Schwann cell development and point to the existence of as yet unidentified cell type-specific bHLH proteins in these cells.

Development of a high capacity multiplex reverse transcriptase-polymerase chain reaction protocol has allowed us to screen lineage related rat islet tumors classified as alpha-, beta-, and delta-like as judged by their hormone profile for differential expression of more than 50 selected genes. We find that in addition to insulin the insulinoma express the normal beta-cell markers Pdx-1, IAPP, and Glut-2, and that these markers are absent from the glucagonoma: a reflection of the normal alpha-cell. Furthermore, this study suggests that the GLP-1, glucagon, GIP, IGF-1, and insulin receptors as well as E-cadherin, R-cadherin, Id-1, and Id-2 are differentially expressed within the islet of
Langerhans. Importantly, insulinoma-specific expression of the recently cloned homeodomain protein Nkx 6.1 predicted beta-cell-specific expression in the normal islet. Immunohistochemistry using antibodies raised against recombinant Nkx 6.1 did indeed localize Nkx 6.1 expression exclusively to the nuclei of normal islet beta-cells. Apart from pancreatic islets only the antral part of the stomach contained Nkx 6.1 mRNA. We multiplex reverse transcriptase-polymerase conclude that reaction-based mRNA profiling is a powerful tool to identify differentially expressed genes within phenotypically related cells and propose that Nkx 6.1 is involved in specifying the unique characteristics of the beta-cell.

caeruloplasmin deficiency is a characteristic biochemical abnormality found in patients with Wilson's disease, but the mechanism of this disease is unknown. Although the phenylenediamine oxidase activity of serum caeruloplasmin is markedly low in patients with Wilson's disease, mRNA of caeruloplasmin exists to some extent. To investigate the deficiency of caeruloplasmin oxidase activity in Wilson's disease, we generated 14 monoclonal antibodies (MAbs) and selected ID1, which had the strongest reactivity, and ID2, which had neutralizing ability. We also established a system to measure active caeruloplasmin specifically using these MAbs. These MAbs and the system will be useful tools in analyzing the active site of caeruloplasmin in patients with Wilson's disease.

Recently it was found that the clinical features of the LEC rat closely resemble those of human Wilson's disease. One of the characteristics of the animal is low levels of serum ceruloplasmin. Therefore, by using LEC rats, we attempted to define molecular basis of the deficiency in active site of ceruloplasmin in Wilson's disease patients. We made 3 monoclonal antibodies, ID2 against active site of ceruloplasmin, ID1 against inactive site of ceruloplasmin, and the remaining one against metallothionein. Using these monoclonal antibodies, we examined immunohistochemical stainings of LEC rat liver tissues, and compared them with those of LEA rats, as a control. ID1 stained the hepatocytes of both LEA and LEC rats, whereas ID2 stained LEA rat hepatocytes only. The results indicated that the ceruloplasmin secreted by LEC rat hepatocytes is mostly in inactive form. The antibody against metallothionein stained LEA rat hepatocytes only. This finding may also indicate that LEC rat hepatocytes express less amount of metallothionein than those of LEA rats.

Three independent mouse monoclonal antibodies (mAbs) ID1 (IgG3), ID2 and ID3 (IgM) were raised against whole cells of a surgically resected human interdigitating cell sarcoma (ICS). In immunoperoxidase staining, these mAbs strongly stained the cytoplasm of ICS neoplastic cells as well as interdigitating cells in normal lymphoid tissues. These mAbs also detected monocyte/macrophages and dendritic cells, although their staining was highly variable depending on tissue

distribution of the cells. Additional immuno-histological and enzyme histochemical study revealed that the neoplastic cells of ICS had cytoplasmic acid phosphatase and membranous alkaline phosphatase activity, and also possessed S100 beta protein, Ki-1 antigen. DAKO-macrophage antigen, and weak vimentin activity. Neither rearrangement of immunoglobulin heavy chain gene nor of T-cell receptor genes was detected in the DNA of ICS by Southern hybridization. These observations provide further confirmation of our previous finding (Nakamura et al. 1988, 1989) that the origin of ICS is interdigitating rather than lymphoid cell, and indicate that our mAbs could be useful as a cellular differentiation marker of interdigitating cells and for diagnosis of ICS.

The primary (1 degree) **antibody** response to (T,G)-A--L shows limited heterogeneity, consisting mostly of side chain-specific antibodies that bind GT and that express the TGB5 idiotype (Id). The secondary (2 degrees) response is very diverse: antibodies that bind the backbone A--L constitute a third of the response, and a high proportion of the side chain-specific antibodies do not bind GT and are TGB5 Id-. To provide a molecular basis for understanding this difference in repertoire expression, we analyzed the Ig genes used by heavy and light chains of 1 degree and 2 degrees side chain-specific anti-(T,G)-A--L hybridoma antibodies (HP). Southern blot restriction analysis and nucleotide sequence analysis of the expressed genes used by three TGB5 Id+ 2 degrees HP showed usage of three different VH genes in two VH gene families (36-60 and J558), different D segments, and two different Vk1 genes (the Vk1A and Vk1C subgroups). Thus, antibody heterogeneity in the 2 degrees response is contributed by combinatorial diversity of distinct germ-line genes. Nucleotide sequence analysis of the expressed genes used by TGB5 Id+ 1 degree HP showed use of highly homologous VH genes in the J558 VH gene family and highly homologous Vk1A genes. The majority of TGB5 Id+ 1 degree HP from different donors gave similar heavy and similar light chain gene rearrangements by Southern blot restriction analysis, after correction for known or potential J region differences. The combined nucleotide sequence and Southern blot restriction analysis data suggest that most 1 degree B cells use the same or very similar VH and Vk genes, i.e., the 1 degree response is paucigenic. Different D segments were used by the TGB5 Id+ 1 degree and 2

degrees HP that were sequenced, and there was no apparent correlation between TGB5 idiotypy and VH, D gene, or JH gene usage. However, all TGB5 Id+ HP sequenced used highly homologous genes from the Vk1 group. Expression of a Vk1 light chain correlates with, but is not sufficient for, TGB5 idiotypy, because one GT-binding, TGB5 Id- HP was found to use a Vk1C subgroup light chain. By Southern blot and nucleotide sequence analysis, the Vk genes used by two TGB5 Id+ 2 degrees HP from xid mice are highly homologous, if not identical to the Vk1A gene(s) used by 1 degree and 2 degrees Id+ HP from wild-type mice.

Intradermal hepatitis B vaccination in an abbreviated schedule. Halsey N A; Reppert E J; Margolis H S; Francis D P; Fields H A Vaccine (ENGLAND) Dec 1986, 4 (4) p228-32, ISSN 0264-410X Journal Code: 8406899

Document type: Clinical Trial; Controlled Clinical Trial; Journal Article; Randomized Controlled Trial

Languages: ENGLISH
Main Citation Owner: NLM
Record type: Completed

Two low-dose intradermal regimens for hepatitis B vaccination were compared with the standard 1 ml dose administered intramuscularly to healthy, 22-42 year old individuals. All regimens were administered in an abbreviated time schedule. Nineteen individuals (ID-1 group) received three 0.1 ml (2 micrograms) doses intradermally at times 0, 1

month and 4 months. Twenty-four individuals (ID-2 group) received two injections of 0.2 ml (4 micrograms) each intradermally at time and one 0.1 ml (2 micrograms) injection 4 months later. Twenty individuals (IM group) received the recommended three 1.0 ml (20 micrograms) doses intramuscularly at times 0, 1 month, and 4 months. No significant adverse reactions were attributable to the intradermal administration of vaccine although the majority of vaccinees developed small areas of induration and hyperpigmentation at the injection site that persisted for several months. One month following the last injection, all vaccinees had developed anti-HBsAg antibodies. One hundred percent of ID-1 and IM vaccinees and 95% of ID-2 vaccinees had protective levels of antibody (greater than or equal to 10 mIU ml-1). The geometric mean titre (GMT) for the IM group (2692 mIU ml-1) was somewhat higher than for the ID-1 (1230 mIU ml-1) and the ID-2 (851 mlU ml-1) groups, but the differences were not statistically significant. Since anti-HBs antibodies are thought to confer protection against hepatitis B, these results suggest that a shortened regimen of intradermal vaccine may be effective in healthy adults. However, no efficacy study has yet been done with intradermal hepatitis B vaccine.

Abstract: Voltage-gated Na+ channels are essential for the normal electrical excitability of neuronal and striated muscle membranes. Distinct isoforms of the Na+ channel alpha-subunit have been identified by molecular cloning, and their functional attributes have been defined by heterologous expression coub pled with electrophysiological

recording. Two closely related Na+ channel alpha-subunit isoforms, hH1 (human heart) and bSkM1 (human skeletal muscle), exhibit differences in their inactivation properties and in their response to the coexpressed beta(1)-subunit. To localize regions that contribute to inactivation and to beta(1)-subunit response, we have exploited these functional differences by studying chimeric channels composed of segments from both hH1 and hSkM1. Chimeras in which one or more of the cytoplasmic interdomain regions (ID1-2, ID2-3, and ID3-4) were exchanged between hH1 and hSkM1 exhibit inactivation properties identical with the background channel isoform, suggesting that these regions are not sufficient to cause gating differences. In contrast, inactivation properties of chimeras composed of approximately equal halves of the two channel isoforms were intermediate between hH1 and hSkM1. Furthermore, the response to the coexpressed beta(1)-subunit was dependent on structures located in the carboxy-terminal half of the ac-subunit, although domains D3, D4, and the carboxy terminal are not singularly responsible for this effect. These data indicate that inactivation differences between hH1 and hSkM1 are determined by multiple alpha-subunit domains.

Abstract: The invention relates to novel endothelial cell-leukocyte adhesion molecules designated ATHERO-ELAM. ATHERO-ELAM molecules are expressed on cultured endothelial cells stimulated with bacterial LPS and selectively mediate the binding of monocytes to the endothelial cells. Monoclonal antibodies specific for ATHEROELAM bind to vascular endothelial cells involved in early atherosclerotic lesions, but not to vascular endothelial cells from uninvolved arterial tissue. ATHERO-ELAM and antibodies directed to ATHERO-ELAM may be used in identifying early atherosclerotic lesions and in treating and preventing atherosclerosis.

The archaeal, bacterial, andeukaryotic genome projects have overwhelmed our ability to experimentally elucidate the function of each novel gene and gene product. To a certain extent, protein functional assignments can be derived via sequence similarity measures and direct primary sequence analysis using methods to predict hydropathy, secondary structure, amphilicity, and antigenicity. Function can also be inferred on the basis of sequence motifs, such as phosphorylation and lipid binding signatures. These methods, provided in DNASTAR's PROTEAN module, can be used to putatively assign roles for novel proteins from the genome explosion as well as clarify function for better known proteins.

The archaeal, bacterial, andeukaryotic genome projects have overwhelmed our ability to experimentally elucidate the **function** of each novel gene and gene product. To a certain extent, protein functional assignments

  Record type: Completed
  The vip3 A gene in a size of 2.3 kb amplified from wild-type Bacillus
thuringiensis strain S184 by PCR was cloned into pGEM-T Easy vector and its
sequence was analysized by DNASTAR. The plasmid pOTP was constructed
by inserting vip3A-S184 gene into the expression vector pQE30 and then was
transformed into E. coli M15. E. coli M15 cells harbouring the plasmid pOTP
were induced with 1 mmol/L IPTG to express 89 kD protein which was confirmed to be Vip3A-S184 by Western blot. Experiments showed that about
19% of Vip3A-S184 proteins were soluble, and others were insoluble proteins
    formed inclusion bodies observed by transmission electron
```

microscopy(TEM). The target protein was purified under the native condition

THIS PAGE BLANK (USDY'

and the polyclonal antibody was prepared by immunizing rabbits. The polyclonal antibody was used to detect Vip3A proteins expressed in Bacillus thuringiensis. Bioassay showed that Vip3A-S184 showed a high toxicity against 3 tested insect larvae including Spodoptera exigua, Spodoptera litura and Helicoverpa armigera.

  The analysis of information in nucleotide and amino acid sequence data
from an investigator's own laboratory, or from the ever-growing worldwide
databases, is critically dependent on well planned and written software.
Although the most powerful packages previously have been confined to
workstations, there has been a dramatic increase over the last few years in
the sophistication of the programs available for personal computers, as the
speed and power of these have increased. A wide choice of software is
available for the Macintosh, including the LaserGene suite of programs from
DNAStar. This review assesses the strengths and weaknesses of
LaserGene and concludes that it provides a useful and comprehensive range
of sequence analysis tools.

ABSTRACT: The main scientific sequence databases of interest for researchers working in the field of bioorganic chemistry are reviewed. Information is given concerning possibilities for rapid access and efficient search for needed information, postal and e-mail addresses, and literature sources in which these databases are comprehensively described.

RECORD TYPE: Abstract LANGUAGE: English

ABSTRACT: SPECIFICATIONS: IBM or compatible microcomputer. DOS 3.0 or higher. Hard drive with at least 20K free storage capacity. Apple Macintosh microcomputer. Both platforms supported with files interchangeable between systems. Manual included. The software supports most printers and most monitors. Cost: LASERGENE 190, 3000.00; LASERGENE 2000, 4500.00; ENTRY/EDIT-restriction Mapping Package, 750.00. DESCRIPTION: The DNASTAR SYSTEM (LASERGENE) is a comprehensive software package for molecular biologists. The software consists of flexible modular systems with the following functions: DNA analysis, Restriction site analysis, Mapping, Protein analysis, Database searching, Sequence comparison, Shotgun sequencing (gel assembly), Sequence entry and editing, SEQ-EASY II digitizer-talker data entry, and System management. Some of the procedures in the DNA analysis software include sequence display, scanning for patterns, creating a 3 dimensional model of the DNA sequence, and the plotting of codon preference values. The restriction site analysis consists of programs for displaying graphic mini-maps of restriction sites, the scanning of sequence and list restriction sites, and creating a file of restriction enzymes, and other operations. The database search functions contains the program "GENEMAN" which searches "GenBank" or "PIR" for keywords, short sequences or combinations of terms and creates subdatabases and the program "PROSCAN", one purpose of which is to search "PIR" for homologies by the Lipman and Pearson method. Some of the attributes of the sequence comparison programs are to allow the comparison of two DNA sequences, the alignment of DNA sequences and the comparison of two proteins. DNASTAR also permits the conversion from other DNA/protein file formats to the DNASTAR format. A modem communication program is included. The programs are interactive and menu driven. The menu driven interface is user-friendly and allows quick and easy access to all the software. A demo is available, at no charge, and there is extensive product support.

## Apoptosis Versus Oncotic Necrosis in Hepatic Ischemia/Reperfusion Injury

HARTMUT JAESCHKE\* and JOHN J. LEMASTERS\*

\*Liver Research Institute, University of Arizona, Tucson, Arizona; and †Department of Cell and Developmental Biology, University of North Carolina, Chapel Hill, North Carolina

Warm and cold hepatic ischemia followed by reperfusion leads to necrotic cell death (oncosis), which often occurs within minutes of reperfusion. Recent studies also suggest a large component of apoptosis after ischemia/reperfusion. Here, we review the mechanisms underlying adenosine triphosphate depletion-dependent oncotic necrosis and caspase-dependent apoptosis, with emphasis on shared features and pathways. Although apoptosis causes internucleosomal DNA degradation that can be detected by terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate nick-end labeling and related assays, DNA degradation also occurs after oncotic necrosis and leads to pervasive terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate nick-end labeling staining far in excess of that for apoptosis. Similarly, although apoptosis can occur in a physiological setting without inflammation, in pathophysiological settings apoptosis frequently induces inflammation because of the onset of secondary necrosis and stimulation of cytokine and chemokine formation. In liver, the mitochondrial permeability transition represents a shared pathway that leads to both oncotic necrosis and apoptosis. When the mitochondrial permeability transition causes severe adenosine triphosphate depletion, plasma membrane failure and necrosis ensue. If adenosine triphosphate is preserved, at least in part, cytochrome c release after the mitochondrial permeability transition activates caspasedependent apoptosis. Mitochondrial permeability transition-dependent cell death illustrates the concept of necrapoptosis, whereby common pathways lead to both necrosis and apoptosis. In conclusion, oncotic necrosis and apoptosis can share features and mechanisms. which sometimes makes discrimination between the 2 forms of cell death difficult. However, elucidation of critical cell death pathways under clinically relevant conditions will show potentially important therapeutic intervention strategies in hepatic ischemia/reperfusion injury.

Hepatic ischemia/reperfusion injury occurs in diverse circumstances, including liver surgery (e.g., a Pringle maneuver during tumor resection or liver trauma),

liver preservation for transplantation, veno-occlusive disease, hemorrhagic shock-resuscitation, and heart failure. Different injury mechanisms contribute to the overall pathophysiology of hepatic ischemia/reperfusion injury. 1-6 Although ischemic stress itself primes cells for damage and will eventually cause cell death, cell injury often does not manifest itself until after the ischemic liver is reperfused. 7

Production of reactive oxygen species, including superoxide, hydrogen peroxide, and hydroxyl radicals, has long been implicated in reperfusion injury, but oxygenindependent factors are important as well, such as tissue pH changes during ischemia/reperfusion.8 Inflammatory responses<sup>2,6</sup> and microcirculatory problems<sup>4</sup> further aggravate injury after reperfusion. Ischemia/reperfusion activates Kupffer cells, the resident macrophages of the liver, and functional inactivation of Kupffer cells attenuates injury during early and late reperfusion.9-13 Kupffer cells activated after reperfusion generate reactive oxygen species, proinflammatory cytokines, chemokines, and other mediators that contribute to postischemic tissue injury and to the systemic inflammatory response syndrome and multiorgan failure that may follow a severe ischemic insult to the liver.14 Together with activated complement factors,15 these inflammatory mediators activate and recruit neutrophils into the postischemic liver, 16,17 which generates even more reactive oxygen<sup>18,19</sup> and releases additional proteases and other degradative enzymes.20 In addition to the inflammatory response, vasoconstriction of sinusoids induced by endothelin-121 promotes heterogeneous closure of many microvessels, which prolongs ischemia in certain areas of the liver even after reperfusion.22

Abbreviations used in this paper: IkB, inhibitor of nuclear factor kB; MPT, mitochondrial permeability transition; NFkB, nuclear factor-kB; TNF, tumor necrosis factor; TUNEL, terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate nick-end labeling.

Most of the described mechanisms of reperfusion injury generally assume cell damage that involves oncotic necrosis. However, several recent reports propose that apoptosis occurs in postischemic heart, liver, and other tissues.<sup>23–25</sup> Postischemic apoptosis would seem to contradict earlier findings of necrotic cell death. Thus, confusion and uncertainty exist concerning the actual mode of cell killing after ischemia/reperfusion. Accordingly, the goal of this overview is to discuss the distinctions between apoptosis and necrosis and to evaluate critically the methods and approaches used to quantify apoptotic and necrotic cell death to reach conclusions regarding the pathophysiological role of each mode of cell death in hepatic ischemia/reperfusion injury.

## **Oncotic Necrosis (Oncosis) in** Ischemia/Reperfusion Injury

The primary stress in ischemia to liver and most other solid tissues is loss of mitochondrial adenosine triphosphate (ATP) production. The resulting ATP depletion leads to cellular swelling, rounding and swelling of mitochondria, dilatation of the endoplasmic reticulum, and formation of plasma membrane protrusions called blebs. 26.27 Blebs are a consequence of ATP depletion and likely represent a response to disrupted cellular volume control and cytoskeletal disturbances. After briefer periods of ischemia/anoxia, bleb formation rapidly reverses after reoxygenation, but necrotic cell death occurs after longer periods. Just before cell death, hepatocytes and hepatic sinusoidal cells develop a metastable state, which is characterized by mitochondrial permeabilization, lysosomal disruption, bleb coalescence and growth, cell swelling, and leakage of anionic solutes. 28-30 Opening of glycine-sensitive anion channels that conduct chloride and various organic anions initiates the metastable state and a phase of rapid colloid osmotic swelling.30 Cell death then occurs by failure of the plasma membrane permeability barrier, often caused by bleb rupture. 28,29 Plasma membrane permeabilization causes release of cellular enzymes and other contents, labeling with vital dyes such as trypan blue, and development of histological changes known as necrosis. The release of cellular contents also initiates an inflammatory response during reperfusion. Over time, macrophages gradually resorb the remnants of the necrotic tissue, which is replaced by scar tissue. Taken together, the observations of postischemic cell swelling, vacuolation, karyolysis, and cell content release, affecting cells in large areas of the tissue in combination with a substantial inflammatory response, are characteristic features of a necrotic cell

death process, more recently renamed oncosis or oncotic necrosis.31

### **Morphological Features of Apoptosis**

The original description of apoptotic cell death was based on morphology. 32 The classic morphological features of apoptosis include cellular shrinkage, nuclear condensation, chromatin margination, and fragmentation of both the nucleus and cytoplasm into apoptotic bodies, which are phagocytosed and degraded by phagocytes, neighboring cells, or both (Figure 1). The original definition of apoptosis describes the cytoplasmic organelles of apoptotic cells as remaining normal in appearance, in marked contrast to necrosis, although many more recent studies show mitochondrial swelling, changes to the endoplasmic reticulum, increased autophagy, and other cytoplasmic changes during apoptosis.33 In classic apoptotic cell death, intracellular contents are not released, and a consequent inflammatory response fails to develop. Functionally, apoptosis eliminates excess and unneeded cells during development and damaged and worn-out tells during normal tissue turnover. Characteristically, apoptosis affects individual isolated cells in a tissue, rather than groups of contiguous cells. Under certain conditions, the apoptotic cell death program may not go to completion. Instead, secondary necrosis supervenes, resulting in the release of proinflammatory intracellular contents.34

# Signaling Mechanisms in **Hepatocellular Apoptosis**

We first briefly review some basic background information on apoptotic signaling pathways in hepatocytes to place into context the discussion of whether postischemic cell death is caused by apoptosis. During the last decade, dramatic progress has been made in the elucidation of the intracellular signaling mechanisms of apoptosis.35-39 A variety of mediators, including tumor necrosis factor (TNF)-α, Fas ligand, and tumor necrosis factor-related apoptosis-inducing ligand (TRAIL), activate a so-called extrinsic pathway to apoptosis. As illustrated for TNF-a in Figure 2, these proapoptotic mediators first bind to their respective receptors, which cause receptor oligomerization and the association of various adapter proteins, including Fas-associated death domain, TNF- $\alpha$  receptor-associated death domain, and TNF- $\alpha$ receptor-associated factor. Fas-associated death domain and TNF-α receptor-associated death domain promote binding of procaspase 8 and its proteolytic activation to catalytic caspase 8. If sufficient amounts of caspase 8 are

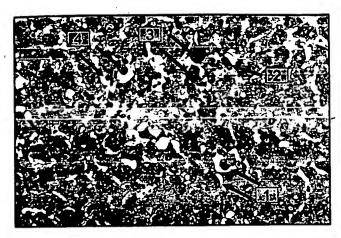

Figure 1. Liver histology of galactosamine-induced apoptosis. Characteristic morphology is shown of rat hepatocytes undergoing apoptotic cell death 6 hours after treatment with galactosamine (500 mg/kg). Features of apoptosis include cell shrinkage (1), chromatin margination (2), chromatin condensation and fragmentation (3), and formation of apoptotic bodies (4).

generated at the receptor, caspase 8 can directly activate procaspase 3 (type 1 pathway).<sup>40</sup> However, in hepatocytes, the receptor signal needs to be amplified through mitochondria (type 2 pathway).<sup>40,41</sup> Caspase 8 cleaves Bid, a BH3 domain-only Bcl-2 family member, to an active fragment, *t*Bid, which translocates to mitochondria. *t*Bid translocation leads to release of soluble proteins from mitochondria that activate caspases and initiate apoptotic nuclear changes.<sup>41</sup> These protein factors include cytochrome *c*, apoptosis-inducing factor, and Smac/Diablo, which reside in the intermembrane space

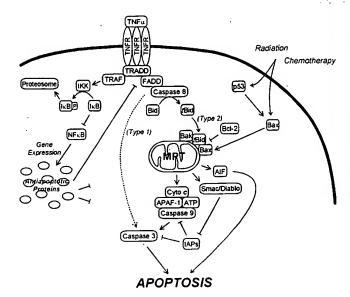

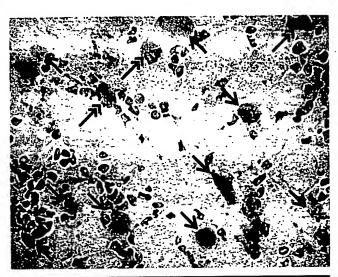

Figure 2. Scheme of apoptotic signaling in hepatocytes. AIF, apoptosis-inducing factor; APAF-1, apoptosis-activating factor-1; IKK, IkB kinase; TRADD, tumor necrosis factor- $\alpha$  receptor-associated death domain; TRAF, tumor necrosis factor- $\alpha$  receptor-associated factor.

between the mitochondrial inner and outer membranes. 62-45

The mechanisms that induce the release of mitochondrial intermembrane proteins remain controversial. In hepatocytes, TNF-α- and Fas-dependent signaling induces the onset of the mitochondrial permeability transition (MPT). The MPT occurs from the opening of a pore, the permeability transition pore, which is highly conductive to solutes of molecular weight up to approximately 1500 daltons. As a consequence of permeability transition pore opening, mitochondria depolarize, uncouple, and undergo large amplitude swelling. This

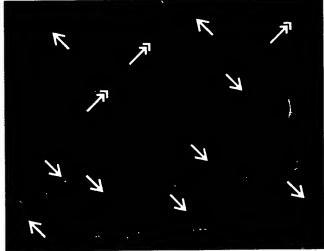

Figure 3. Trypan blue staining and TUNEL labeling after cold liver storage and orthotopic rat liver transplantation. A rat liver was stored in cold University of Wisconsin solution for 44 hours and transplanted into a recipient rat. After 15 minutes of implantation, the liver graft was infused with trypan blue and fixed. The *upper panel* shows trypan blue uptake into the nuclei of nonviable cells, indicating oncotic necrosis, whereas the *lower panel* shows TUNEL-positive nuclei labeled with green fluorescence, indicating DNA strand breaks. Note that all TUNEL-positive cells stain with trypan blue (*arrows*), whereas some trypan blue–labeled cells stain weakly or not at all with TUNEL (*double arrows*). (X.-X. Peng, et al., unpublished data, January 2003).

swelling causes a rupture of the outer membrane and a release of proteins from the intermembrane space. Other mechanisms for cytochrome c release also seem to exist. In some models, tBid interaction with either Bax or Bak, 2 other proapoptotic members of the Bcl-2 family, forms channels in the mitochondrial outer membrane that release cytochrome c and a number of other, larger proteins from the intermembrane space. The nature and composition of these channels, however, remain poorly understood. A3, A7, A8 Bcl-2 and other antiapoptotic Bcl-2 family members block cytochrome c release. The mechanism for the antiapoptotic action of Bcl-2 may involve blockade of the MPT and/or antagonism of Bax/Bak-dependent pore formation in the mitochondrial outer membrane.

After its release from mitochondria, cytochrome c forms a complex with apoptosis-activating factor-1, ATP (or deoxyadenosine triphosphate), and procaspase 9 (Figure 2). This complex, called an apoptosome, proteolytically activates caspase 9, which in turn activates procaspase 3 to caspase 3.<sup>49</sup> Through action on a variety of substrates, caspase 3 activity initiates the final execution stages of apoptosis, including cell shrinkage, surface blebbing, internucleosomal DNA hydrolysis, phosphatidyl serine externalization on the plasma membrane, chromatin margination, and nuclear lobulation.

In general, the type 2 apoptotic signaling pathway through the mitochondria, as it occurs in hepatocytes, is faster than the type 1 pathway and can be better regulated. However, if the type 2 pathway is blocked by inhibition of the MPT with cyclosporin A, caspase 3 activation and apoptosis will still occur, but at a slower rate, via a type 1 pathway, but without mitochondrial depolarization, the MPT, or cytochrome c release (Figure 2).50 Adding to this redundancy is the so-called intrinsic

pathway to apoptosis<sup>51</sup> (Figure 2). Such pathways may or may not involve p53-dependent gene expression but may activate apoptosis by still incompletely understood mechanisms through translocation of Bax and other proapoptotic Bcl-2 family members to the mitochondria to cause cytochrome c release and the activation of caspases 9 and 3.

Death receptors also initiate survival signals. For example, ligation and oligomerization of TNF- $\alpha$  receptors and Fas promote receptor association of another adapter protein, TNF-α receptor-associated factor. TNF-α receptor-associated factor in turn initiates inhibitor of nuclear factor-kB (IkB) kinase activation, IkB phosphorvlation, and subsequent degradation of IkB in proteosomes. The disappearance of IkB de-represses nuclear factor-kB (NFkB), which translocates to the nucleus to induce expression of several antiapoptotic genes that prevent apoptosis from occurring, including inhibitorof-apoptosis proteins (Figure 2).52,53 Survival signaling through NFkB is so strong that to induce apoptosis in cultured hepatocytes, NFkB-dependent gene expression must be blocked by using protein or messenger RNA synthesis inhibitors or by expressing an IkB superrepressor that has been mutated to lack a phosphorylation site for IkB kinase.54

# Assessment of Apoptotic Cell Death

As a result of an increasing understanding of the mechanisms and pathways to apoptotic cell death, more and more biochemical and immunologic assays are being developed and used to characterize apoptosis (Table 1). Today, apoptosis can be monitored in vitro and in vivo

Table 1. Assays for Apoptosis

Nuclear morphology (chromatin condensation and nuclear lobulation/fragmentation) in histological sections and after fluorescent staining with DAPI, propidium iodide, and so on

Internucleosomal DNA cleavage (DNA ladder after starch gel electrophoresis; ELISA for DNA fragments)

TUNEL and related assays (in situ detection of double-stranded DNA breaks)

Annexin V (phosphatidyl serine externalization)

Caspase assays (especially caspases 3, 2, 8, and 9)

Enzyme assays using fluorogenic substrates

Immunocytochemistry with specific antibodies against activated caspases

Western blotting to show a decrease of the proenzyme and the appearance of active fragments

Cleavage of caspase substrates (e.g., PARP cleavage)

Nuclear staining with supravital dyes for secondary necrosis (trypan blue; propidium iodide)

Mitochondrial depolarization assessed with potential-indicating fluorophores (rhodamine 123, tetramethylrhodamine methylester, JC-1, and so on)

Cytochrome c release into cytosol (Western blot; immunocytochemistry)

Translocation of proapoptotic proteins (Bax, Bid, and so on) to mitochondria; proteolytic cleavage of Bid (Western blot; immunocytochemistry)

DAPI, 4',6-diamidino-2-phenylindole; ELISA, enzyme-linked immunosorbent assay; JC-1, 5,5',6,6'-tetrachloro-1,1',3,3'-tetraethylbenzimidazolyl carboxycyanine iodide. PARP, poly (adenosine diphosphate-ribose) polymerase.

by such diverse techniques as enzyme assays for activated caspases, Western blot analyses for caspase processing; annexin V labeling for phosphatidyl serine externalization, cleavage of poly (adenosine diphosphate-ribose) polymerase and other targets of caspase 3 proteolytic action, trypan blue and propidium iodide staining, and mitochondrial depolarization and cytochrome c release; in addition to classic morphological criteria. In particular, a distinctive form of random DNA cleavage between nucleosomes occurs in apoptosis, which produces DNA fragments in multiples of approximately 190 base pairs (the length of DNA from 1 nucleosome to the next). This pattern of DNA cleavage produces a characteristic laddering pattern after gel electrophoresis. Other methods to assess DNA cleavage are by enzyme-linked immunosorbent assay kits that detect DNA fragments and by the terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate nick-end labeling (TUNEL) assay (Table 1).

It is important to note that apoptosis represents a constellation of events, and no single change is necessarily a required event in apoptosis or is unique to apoptosis. For example, mitochondrial depolarization, swelling, and cytochrome c release also typically occur in oncotic necrosis, and the trypan blue and propidium iodide labeling of so-called late apoptosis actually represents a phenomenon of secondary necrosis associated with loss of plasma membrane integrity. Necrotic cell death also leads to annexin V labeling,55 because after lysis of the plasma membrane, annexin V gains entrance to the interior of cells and the internal surface of the plasma membrane, where phosphatidylserine normally resides. Caspase 3 activation is perhaps most uniquely associated with apoptosis, but not all forms of apoptosis require caspase 3 activation.

Necrosis also causes DNA cleavage, although such cleavage is not characteristically internucleosomal. On gel electrophoresis, such cleavage leads to a smear of many different molecular weight fragments rather than a ladder pattern of multiples of 190 base pairs. However, DNA fragmentation with a ladder pattern was also reported during necrosis. 56,57 Calcium-dependent activation of endonucleases may be responsible for this effect.58 Techniques such as the TUNEL assay may not distinguish the internucleosomal DNA cleavage of apoptosis from the much less ordered DNA cleavage of necrosis. In liver and other tissues, TUNEL labeling occurs during ischemic necrosis and after toxicant-induced necrotic cell killing.59-61 Indeed, after reperfusion of livers stored for transplantation, the same cells showing TUNEL labeling, a presumptive indicator of apoptosis, also labeled with trypan blue, an indicator of oncotic necrosis, whereas not all trypan blue-stained cells labeled with TUNEL (Figure 3). These observations are consistent with postnecrotic DNA hydrolysis as the basis for TUNEL conversion in necrotic tissue, as previously proposed.<sup>59-61</sup>

Overall, the most reliable method to identify apoptotic cell death is morphology. Vital dyes and simple histology can readily visualize nuclear morphology (chromatin condensation and fragmentation). Once apoptosis as the mode of cell death is established by the characteristic morphological changes, any number of other parameters listed in Table 1 can be used to further support the hypothesis and delineate specific signaling pathways.

# Apoptotic Cell Death During Hepatic Ischemia/Reperfusion

The first report of apoptotic cell death during hepatic ischemia/reperfusion appeared in 1996.24 Similar reports of postischemic apoptosis have appeared for heart, brain, and other organs. 23.62.63 In liver after 60 minutes of warm ischemia, the number of apoptotic hepatocytes evaluated by nuclear morphology increases during the first 24 hours of reperfusion.24 Using the TUNEL assay, another study identified apoptotic hepatocytes in human allografts after transplantation.64 Subsequent studies reported that sinusoidal endothelial cells undergo apoptosis during cold ischemia/reperfusion<sup>25</sup> and that both sinusoidal endothelial cells and hepatocytes undergo apoptosis after warm ischemia/reperfusion.65 These observations were based largely on fluorescence TUNEL assays and DNA laddering in gels. In addition, electron microscopy showed that single cells meet the morphological definition of apoptosis. 25,65 Further, pancaspase inhibitors attenuated reperfusion injury after warm and cold ischemia. 66.67 By the criteria of TUNEL labeling, 60% to 80% of sinusoidal endothelial cells and hepatocytes undergo apoptosis within 6 hours of reperfusion.65,67 Further studies suggested that Kupffer cells and platelets are responsible for inducing apoptosis in these liver cells through the release of TNF-α.68.69

Despite the growing literature on apoptotic cell death after hepatic ischemia/reperfusion, concerns exist regarding the interpretation of these results and the relevance of apoptosis in the pathophysiology of reperfusion injury. The onset of necrotic cell death as judged by enzyme release and staining with trypan blue and propidium iodide occurs within minutes of reperfusion (see Figure 3).<sup>70–72</sup> After warm ischemia, reperfusion-induced oncotic necrosis occurs predominantly in hepatocytes and is accompanied by enzyme release.<sup>71,73</sup> After cold ischemia

during liver preservation for transplantation, necrotic death occurs nearly exclusively in sinusoidal endothelial cells and is accompanied by relatively little enzyme release because of the much smaller cytoplasmic mass of the endothelial cells.7.70 The extent of this reperfusioninduced necrotic cell killing correlates well with graft failure after transplantation. When strict morphological criteria in combination with the TUNEL assay are used, apoptosis of endothelial cells and hepatocytes after 45 to 120 minutes of warm ischemia can be confirmed, but quantitatively apoptosis never exceeds 2% of the liver cells at risk.<sup>74</sup> Furthermore, necrotic cell death, identified by cell swelling, karyorrhexis, karyolysis, and vacuolization, accounts for more than 90% of all cell death, although many of the necrotic cells are TUNEL positive.74 The relatively minor component of apoptotic cell death after reperfusion is consistent with several other reports.<sup>24,75–77</sup> The limited amount of apoptotic cell death also correlates with limited or absent activation of caspases.<sup>74</sup> In contrast, during Fas- and TNF receptor-induced apoptosis in vivo, which affects approximately 15%–30% of hepatocytes, caspase 3 activity levels increase 10- to 20-fold or more, and extensive processing of procaspase 3 occurs<sup>78,79</sup>—features that are nearly absent after ischemia/reperfusion.<sup>74</sup>

Characteristically, apoptosis occurs in individual isolated cells. Even if large numbers of hepatocytes are induced in vivo to undergo apoptosis after activation of Fas or TNF receptors, individual cells rather than groups of contiguous cells show apoptotic features (Figure 4B). In contrast, oncotic necrosis typically occurs in confluent areas of adjacent cells (Figure 4C and D).<sup>61,80,81</sup> After

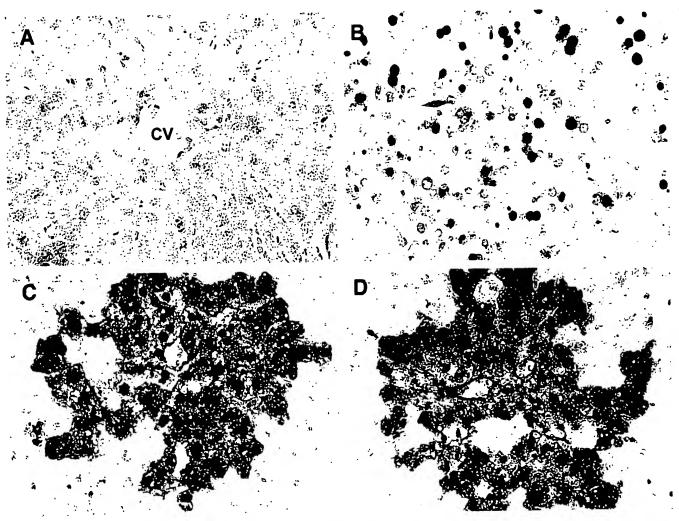

Figure 4. Hepatic TUNEL staining in TNF-α-induced apoptosis and acetaminophen-induced oncotic necrosis. Mice were untreated (A), received 700 mg/kg galactosamine and 100 μg/kg endotoxin for 6 hours (B), or were treated with 300 mg/kg acetaminophen for 4 hours (C) or 6 hours (D). The assay shows a selective nuclear staining of individual hepatocytes during apoptosis (B) compared with the nuclear/cytosolic staining of contiguous cells in the centrilobular region of early oncotic necrosis after acetaminophen (C). Because of the more extensive karyolysis at later stages of oncotic necrosis, nuclear staining is less prominent in most cells compared with the cytosolic staining after 6 hours of acetaminophen treatment (D). CV, central vein.

hepatic ischemia/reperfusion, this necrosis typically occurs in the pericentral and midzonal regions of the hepatic lobule, because these regions are furthest removed from the oxygen supply.<sup>5,74</sup> These observations are consistent with the conclusion that the main mode of cell death during reperfusion injury is oncotic necrosis.

Another argument for apoptosis as the principal mode of cell killing after ischemia/reperfusion is the protective effect of Bcl-2 overexpression.82 Bcl-2 interrupts apoptotic signaling at the level of the mitochondria38 and prevents Fas-induced hepatocellular apoptosis.83 However, Bcl-2 overexpression also inhibits necrotic cell death in hepatocytes and other cell types, possibly by inhibiting the MPT.84.85 Oncosis can have other similarities to apoptosis, such as translocation of Bax to the mitochondria86 and release of mitochondrial cytochrome c (without caspase 3 activation)87 during acetaminopheninduced oncotic necrosis. Thus, identification of apoptosis as the principal mode of cell death requires evaluation of several parameters, which should qualitatively and quantitatively correlate with the extent of the assumed apoptosis.

Despite the predominance of necrosis over apoptosis after hepatic ischemia/reperfusion, several groups report protection by caspase inhibitors during ischemia/reperfusion.66,67 However, protection may be rather modest, even with potent pancaspase inhibitors. For example, pancaspase inhibitors delay liver graft failure after prolonged cold ischemic storage by only approximately a day, without improvement of long-term graft survival.67 This small and ultimately clinically irrelevant prolongation of survival may be due to anti-inflammatory effects, because pancaspase inhibitors block interleukin-1-converting enzyme (later renamed caspase 1), an enzyme involved in activating interleukin-1 and some other proinflammatory cytokines.88 Apoptosis in a pathophysiological setting often promotes inflammation,89 which in turn can extend and accelerate tissue injury.<sup>17</sup> During Listeria infection, hepatocellular apoptosis can promote neutrophil recruitment into the liver.90 Moreover, TNFinduced parenchymal apoptosis triggers neutrophil transmigration and massive aggravation of the injury in an endotoxemia model.91,92 Although the exact signaling mechanisms are not completely understood, apoptotic hepatocytes generate CXC chemokines,93 which can signal neutrophil infiltration. A proinflammatory role of apoptosis in hepatic ischemia/reperfusion injury is also implied by findings that pancaspase inhibition decreases neutrophil recruitment into the liver, with attenuation of reperfusion injury.94 Thus, apoptosis, even if limited to a relatively small number of cells, still has the potential to affect overall injury by contributing to the amplification of the inflammatory response.

## **Necrapoptosis**

Part of the confusion concerning the roles of apoptosis and necrosis in ischemia/reperfusion and other forms of hepatic injury arises from the assumption that apoptotic and necrotic mechanisms are distinct and separate when, in fact, these mechanisms can be shared. In particular, the MPT plays an important role in oncotic necrosis, as well as in apoptosis. In ischemia, anaerobic glycolysis and ATP hydrolysis during ischemia rapidly decrease tissue pH, which protects strongly against necrotic cell killing despite profound ATP depletion. 95,96 Payback occurs when physiological pH returns after reperfusion, and the recovery of normal intracellular pH is an independent factor for precipitating lethal cellular reperfusion injury. 70,71,97 The mechanism of pH-dependent reperfusion injury involves onset of the MPT, a phenomenon that is inhibited by pH <7. Initially after reperfusion of hepatocytes in a cell culture model, mitochondria begin to repolarize, but as the intracellular pH approaches 7, mitochondria undergo inner membrane permeabilization, depolarization, and large-amplitude swelling.72

After onset of the MPT, mitochondrial uncoupling and activation of the mitochondrial uncoupler-stimulated adenosine triphosphatase lead to profound ATP depletion and ATP depletion-dependent necrotic cell death.72 Cyclosporin A, a specific inhibitor of the MPT, prevents MPT-induced mitochondrial depolarization, inner membrane permeabilization, and ATP exhaustion after reperfusion and blocks the necrotic cell killing that ensues. The importance of ATP depletion is illustrated by the ability of the ATP-generating glycolytic substrate fructose to prevent this necrotic cell death. Only 15% to 20% of normal ATP is sufficient to prevent such necrotic cell killing.98.99 Cytoprotection by fructose is downstream of the MPT, because fructose does not prevent the mitochondrial depolarization and inner membrane permeabilization induced by MPT-inducing treatments. 100 MPT-dependent necrotic cell death in models of ischemia/reperfusion to cultured hepatocytes is not blocked by caspase inhibitors and occurs without TUNEL staining.101 The absence of TUNEL staining may reflect the release and dilution into the medium of nucleases after plasma membrane permeabilization.

However, when necrotic cell death is prevented by fructose, caspase 3-dependent apoptosis occurs instead, as documented by nuclear morphology, TUNEL labeling, and caspase activation. Occlosporin A, a specific

blocker of the MPT, still prevents this apoptosis, as do caspase inhibitors. Thus, the MPT is an obligatory event in both necrotic and apoptotic cell killing after ischemia/reperfusion. But how can one event, the MPT, lead to two such disparate events?

The onset of MPT leads to large-amplitude mitochondrial swelling, rupture of the outer membrane, and release of cytochrome c and other proteins from the intermembrane space between the mitochondrial inner and outer membranes. As discussed previously, cytochrome cinteracts with apoptosis-activating factor-1 to promote caspase 9 activation, which then activates caspase 3. However, cytochrome c-dependent activation of caspase 9 requires ATP or the less abundant deoxyadenosine triphosphate.42 Accordingly, the presence or absence of ATP can act as a "switch" between apoptosis and necrosis. 102-104 When reperfusion leads to both MPT onset and ATP depletion, apoptotic signaling is blocked at the level of the apoptosome, and necrosis occurs as a direct result of the failure of ATP regeneration (Figure 5). By contrast, if glycolytic substrate is available, profound ATP depletion is prevented, and necrosis does not occur. Instead, ATP-dependent apoptotic signaling occurs that is initiated by cytochrome c release after mitochondrial swelling. In cell-free extracts, the apparent K<sub>M</sub> of ATP for activating apoptosomes is approximately 0.4 mmol/ L,105,106 which is only approximately 10% of the ATP concentration of normoxic hepatocytes. Thus, the amount of ATP needed to prevent necrosis (15%-20% of normoxic levels) is more than enough to permit cytochrome c-dependent caspase 9 and caspase 3 activation Similarly, in hepatocytes exposed to calcium ionophore, the balance between ATP depletion after the MPT and ATP generation by glycolysis determines whether necrotic or apoptotic cell death occurs.100 Thus, one mitochondrial event, the MPT, can lead to both apoptosis and necrosis (Figure 5). Consistent with these in vitro findings, the mode of hepatic cell death can be apoptosis after resuscitation after a shorter period of hemorrhagic shock when cellular ATP levels fully recover but can be oncotic necrosis after a longer period of shock when ATP levels remain suppressed after resuscitation. 102

Just as a necrotic process can be converted to an apoptotic one, a process that starts with classic apoptotic signaling may switch to necrosis if ATP depletion or another change leads to breakdown of the plasma membrane permeability barrier. Apoptosis resulting in such secondary necrosis typically occurs during Fas antibodyinduced hepatocellular injury in vivo. In Fas receptor ligation—dependent liver injury, mitochondrial cytochrome c release, activation of the caspase cascade, DNA

# Necrapoptosis

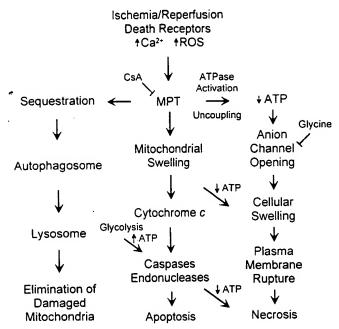

Figure 5. Scheme of mitochondrial permeability transition (MPT)dependent events in necrapoptosis. Ischemia/reperfusion, deathreceptor activation, mitochondrial Ca2+ loading, and reactive oxygen species (ROS) are some of the events that promote onset of the MPT. If MPT onset occurs in relatively few mitochondria, the organelles become sequestered into autophagosomes for lysosomal digestion, a process that eliminates the damaged and potentially toxic mitochondria. When the MPT involves more mitochondria, mitochondrial swelling leads to outer membrane rupture and cytochrome c release. Provided that ATP is available from glycolysis and still-intact mitochondria, cytochrome c activates downstream caspases and other executioner enzymes of apoptosis. When MPT onset is abrupt and involves most mitochondria, ATP becomes profoundly depleted, which blocks caspase activation. Instead, ATP depletion leads to the opening of a glycine-sensitive organic anion channel to initiate a metastable state that culminates with plasma membrane rupture and the onset of necrotic cell death. If ATP depletion occurs during downstream apoptotic signaling, then secondary necrosis may supervene. CsA, cyclosporin A.

fragmentation, and morphological changes characteristic of apoptosis occur before the onset of secondary necrosis, with hepatocellular enzyme release and inflammatory changes. 34,78,79 Thus, in an apoptotic process that ultimately culminates in secondary necrosis, apoptotic mechanisms nonetheless remain clearly identifiable by morphological and biochemical parameters at earlier times.

The ability of a necrotic process to be converted to an apoptotic one and vice versa illustrates that apoptotic and necrotic cell death are not necessarily distinct and independent events. To the contrary, pathways leading to necrosis and apoptosis can be shared, a phenomenon called *necrapoptosis* or *aponecrosis*.<sup>107,108</sup> In necrapoptosis, events such as the MPT initiate a chain reaction that

culminates in either apoptosis or necrosis, depending on other variables, such as ATP supply (Figure 5). By inducing the MPT, ischemia/reperfusion causes both apoprosis and necrosis, although in a particular circumstance one or the other may predominate. The concept of necrapoptosis explains why features of apoptosis and necrosis often coexist in liver and other tissues, especially afterpathologic insults such as ischemia/reperfusion or druginduced liver injury. Recent work also suggests that limited onset of the MPT induces autophagy, a process by which effete, damaged, or superfluous mitochondria and other organelles are eliminated from cells by lysosomal degradation. 109 Thus, the concept of MPT-dependent necrapoptosis explains how injury can progress from reversible changes associated with tissue repair to apoptosis and then to necrosis. When the MPT occurs in only a few mitochondria, autophagy is stimulated, and the involved mitochondria are segregated for lysosomal degradation without stimulation of apoptotic signaling. With greater injury and more widespread MPT induction, apoptosis develops because of cytochrome *t*-dependent caspase activation. With even greater injury and MPT induction, ATP decreases to levels that no longer support apoptotic signaling, and oncotic necrosis develops instead (Figure 5).

#### **Conclusions**

In liver, oncotic necrosis and apoptosis share features and mechanisms. DNA degradation after necrosis causes TUNEL labeling, which may be incorrectly interpreted as apoptotic cell death. During apoptosis in pathophysiological settings, inflammatory responses and enzyme release occur that resemble a necrotic process. Frequently, oncotic necrosis and apoptosis coexist after toxic, hypoxic, and inflammatory liver injury. The coexistence of the 2 patterns of cell death likely reflects shared mechanistic pathways. Experimental or clinical settings will determine whether cells die predominantly by apoptosis or oncotic necrosis. Therefore, it is important to evaluate critical cell death pathways under clinically relevant conditions to discover new therapeutic intervention strategies in hepatic ischemia/reperfusion injury.
